Problem Solving Workshop

Phase 1: Foundations

Instructor: Abhishek Bansal Academic Year: 2025

Course Overview

This two-week workshop introduces foundational problem-solving techniques through classic puzzles, algorithmic strategies, and real-world modeling exercises. Students will build confidence in recursion, search algorithms, data structures, and collaborative design.

Phase 1 Curriculum Overview

1. Sudoku – Baseline Quiz

- Sudoku, logic-grid, and handshake-count puzzles (N(N-1)/2)
- Survey: "How did you solve each?"

Outcome: Gauge current skills and problem-solving intuition.

2. N-Queens Backtracking

- Explain rules
- Code stub: def place_queens(row, board): ...
- Test on N=4 and N=8

Outcome: Hands-on recursion and pruning.

3. Sudoku Solver

- Constraint propagation and backtracking
- Fill in logic for provided Python function signature

Outcome: Reinforce state-space search.

4. Graphs via Word Ladders – Mazes

- Introduction to graphs (nodes, edges)
- BFS/DFS on word ladders
- Maze-path visualization

Outcome: Bridge puzzles to graph algorithms.

5. Group Challenge – Extensions

- Teams choose from N-Queens, Sudoku, word ladders, mazes, or optional puzzles (Lights Out, Josephus, Tower of Hanoi, Coin Change, Word Search)
- Sketch and pitch an improved solution

Outcome: Collaboration and peer teaching.

6. Queues – Real-World Simulation

- Live-code a bank-line simulator using a queue
- Stack demo: undo/redo

Outcome: Apply data structures in real-world contexts.

7. Game AI – Tic-Tac-Toe

- Provide stub: def minimax(board, player): ...
- Implement and play versus AI

Outcome: Expose decision-tree logic.

8. Event-Driven Modeling: Traffic / Queue

- Model traffic lights or a bank queue with events
- Discuss real-world modeling challenges

Outcome: Experience event-driven thinking.

9. Ideation Workshop

- Brainstorm campus/community problems (library booking, canteen queues)
- Structured voting on top ideas

Outcome: Nurture interdisciplinary vision.

10. Mini-Pitch – Reflection

- Three-minute team pitches with solution outlines
- Reflection: "What did we learn?"

Outcome: Build confidence and prepare for Phase 2 capstone.

Setup Instructions

Students should follow these steps to access materials:

- Join our Replit Classroom: Click here
- Complete the Quiz on Google Forms: Click here
- View the Progress Tracker: Click here

Puzzles & Baseline Quiz

Ice-Breaker Puzzles

Complete the following exercises in 20 minutes:

- a. **Sudoku** (4×4 grid): Fill each row, column, and 2×2 block with numbers 1–4 exactly once.
- b. **Logic Grid Puzzle**: Three students (A, B, C) each solved *one* of three puzzles (maze, riddle, sudoku-mini) in *one* of three times (5, 10, 15 minutes), and no two students chose the same puzzle or time.
 - A did **not** take 5 minutes.
 - The riddle was solved in 10 minutes.
 - C solved the maze.
 - The sudoku-mini was completed in the shortest time (5 minutes).

Determine who solved which puzzle and in what time.

c. **Handshake Count**: In a group of 7, every pair shakes hands exactly once. How many total handshakes occur?

Baseline Quiz

Answer the following in the next 10 minutes:

- 1. Compute the handshake count for N=7 and verify using the formula $\frac{N(N-1)}{2}$.
- 2. Write pseudocode for computing handshake count for a general N:

```
function handshakeCount(N):
    # Each of N people shakes hands with N-1 others
    # Divide by 2 to avoid double-counting
    return N * (N - 1) / 2
```

3. Reflect: Which problem-solving heuristic did you use most (decomposition, pattern recognition, abstraction)?

Backtracking I – N-Queens

Problem Description

Place one queen in each row of an $N \times N$ chessboard so that no two queens attack each other. A queen attacks along its row, column, and both diagonals.

Recursive Pseudocode

Use the following stub to implement your solution:

```
function placeQueens(row, board):
  if row > N:
    printSolution(board)
    return
  for col = 1 to N:
    if isSafe(row, col, board):
      board[row] = col
      placeQueens(row + 1, board)
      board[row] = 0 # backtrack
function isSafe(r, c, board):
  for prevRow = 1 to r - 1:
    prevCol = board[prevRow]
    if prevCol == c or
       abs(prevCol - c) == abs(prevRow - r):
      return false
  return true
```

Try it online: Run the N-Queens demo on Replit

Exercise

- Implement the pseudocode and print one valid arrangement for N=4.
- Extend your code to count all solutions for N=4 and report the total.
- *(Optional)* Test your solver for N=8 and note the number of solutions.
